Quadratic forms, generalized Hamming weights of codes and curves with many points.

Gerard van der Geer and Marcel van der Vlugt

arXiv:alg-geom/9412011v1 13 Dec 1994

Introduction. alg-geom/9412011In the interaction between algebraic geometry and classical coding theory the correspondence between words in trace codes $\mathcal{C}$ and Artin-Schreier curves over finite fields is a central theme. This correspondence can be extended to a relation between subcodes of $\mathcal{C}$ and fibre products of Artin-Schreier curves. As a consequence weights of words and subcodes are related to numbers of rational points on curves, where low weight words and subcodes yield curves with many rational points. Subcodes in which all non-zero words have minimum weight lead to curves with a large number of points compared to known upper bounds.

The most general upper bound for the number of rational points $\#C(\mathbb{F}_q)$ on a smooth projective curve C of genus g over a finite field with q elements $\mathbb{F}_q$, is

$$\#C(\mathbb{F}_q) \leq q + 1 + g[2\sqrt{q}] \tag{1}$$

which is Serre's improved form of the Hasse-Weil upper bound (see [Se]). Here $[x]$ is the greatest integer function.

Trace codes which are subcodes of (binary) second-order Reed-Muller codes have proved to be successful in the construction of curves with many points. The words in these trace codes correspond not only to algebraic curves but also to *quadratic forms* over $\mathbb{F}_2$. Using the well known theory of quadratic forms we shall develop a simple tool to construct subcodes in such trace codes consisting of minimum weight words, by which we obtain curves carrying many rational points.

We shall compare our curves with the curves in the table of Wirtz [W]. This table lists for many small fields $\mathbb{F}_q$ and genera g an interval [A,B] where A means that there exists a curve C of genus g over $\mathbb{F}_q$ with A rational points, while B is an upper bound.

Although we restrict to binary codes, a slightly modified construction can be applied to trace codes over $\mathbb{F}_p$ with odd prime p.

The paper is organized as follows. In Section 1 we recall elementary facts on fibre products of curves and generalized Hamming weights of codes and we introduce the codes we shall consider. In Section 2 the relation between the codes and quadratic forms is explained. Then we describe the construction of low weight subcodes in case $q = 2^m$ with m odd in Section 3 and in Section 4 we give applications of the construction. In the last Section we discuss the case $q = 2^m$ with m even.

§1. Fibre products of curves and generalized Hamming weights.

In a series of papers [GV-2, 3, 4] we showed that there is a relation between generalized Hamming weights of trace codes and the number of rational points on fibre

alg-geom/9412011

products of curves associated to these trace codes. We used that relation to construct curves with many rational points. In this section we recall some of the ingredients.

Let $\mathbb{F}_q$ be a finite field of cardinality $q = 2^m$. For $0 < h \leq [m/2]$ we consider the finite dimensional $\mathbb{F}_q$-vector space of 2-*linearized polynomials*

$$R_h = \{R = \sum_{i=0}^{h} a_i x^{2^i} : a_i \in \mathbb{F}_q\}.$$

The vector space R_h defines a binary linear code $\mathcal{C}_h$ by applying the trace map Tr from $\mathbb{F}_q$ to $\mathbb{F}_2$:

$$\mathcal{C}_h = \{c_R = (\mathrm{Tr}(xR(x))_{x \in \mathbb{F}_q^*} : R \in R_h\}.$$

The code $\mathcal{C}_h$ is a subcode of the punctured binary second-order Reed-Muller code and for $h = 1, 2$ the codes $\mathcal{C}_h$ are the duals of the 2- and 3-error correcting BCH codes of length $q - 1$.

To a non-zero word c_R of $\mathcal{C}_h$ we associate a non-singular projective curve C_R with affine equation.

$$y^2 + y = xR(x).$$

It is an Artin-Schreier cover of $\mathbb{P}^1$. If $a_h \neq 0$ the curve C_R has genus 2^{h-1} and the weight $w(c_R)$ of the word c_R is related to the number of $\mathbb{F}_q$-rational points on C_R, by the equation

$$w(c_R) = q - (\#C_R(\mathbb{F}_q) - 1)/2.$$

If $\mathcal{D} \subset \mathcal{C}_h$ is a r-dimensional subcode we associate a curve $C^{(\mathcal{D})}$ to $\mathcal{D}$ as follows. Choose a $\mathbb{F}_2$-basis $c_{R_1}, ..., c_{R_r}$ of $\mathcal{D}$ and set

$$C^{(\mathcal{D})} = \text{ Normalization of } C_{R_1} \times_{\mathbb{P}^1} \times ... \times_{\mathbb{P}^1} C_{R_r},$$

where the fibre product is taken with respect to the canonical projections $\varphi_{R_i} : C_{R_i} \to \mathbb{P}^1$. Up to isomorphism this does not depend on the chosen basis.

In [G-V2] we proved the relation

$$t_{\mathrm{Frob}} C^{(\mathcal{D})} = \sum_{c_{R_i} \in \mathcal{D} - \{0\}} t_{\mathrm{Frob}}(C_{R_i}), \tag{2}$$

between the traces of Frobenius of the curves involved. Here the trace of Frobenius for a curve C over $\mathbb{F}_q$ is defined as $t_{\mathrm{Frob}} = q + 1 - \#C(\mathbb{F}_q)$. Furthermore, we have the relation for the genera g of the curves involved:

$$g(C^{(\mathcal{D})}) = \sum_{c_{R_i} \in \mathcal{D} - \{0\}} g(C_{R_i}). \tag{3}$$

An important parameter of a subcode $\mathcal{D}$ of a code $\mathcal{C}$ is its *weight* $w(\mathcal{D})$, by which we mean the number of coordinate places for which at least one word of $\mathcal{D}$ has a non-zero coordinate. In the binary case we have the relation

$$w(\mathcal{D}) = \frac{1}{2^{r-1}} \sum_{d \in \mathcal{D}} w(d).$$

The *r-th generalized Hamming weight* $d_r(\mathcal{C})$ of $\mathcal{C}$ is defined by

$$d_r(\mathcal{C}) = \min\{w(\mathcal{D}) : \mathcal{D} \text{ is a } r-\text{dimensional subcode of } \mathcal{C}\}.$$

If there exists a r-dimensional subcode in which all non-zero words have minimum weight, which we shall call a *minimum weight subcode*, then

$$d_r(\mathcal{C}) = (2^r - 1)d_1(\mathcal{C})/2^{r-1}. \tag{4}$$

In our case where $\mathcal{C} = \mathcal{C}_h$ we recall the following proposition from [G-V2].

(1.1) Proposition. *The weight $w(\mathcal{D})$ of the r-dimensional subcode $\mathcal{D} \subset \mathcal{C}_h$ satisfies*

$$w(\mathcal{D}) = q - (\#C^{(\mathcal{D})}(\mathbb{F}_q) - 1)/2^r. \qquad \square$$

We immediately see that subcodes of low weight correspond to fibre products with many points.

§2. Quadratic forms and codes.

To a non-zero word $c_R \in \mathcal{C}_h$ (or to $R \in R_h - \{0\}$) we can associate not only a curve but also a *quadratic form*. Indeed, the expression

$$Q_R(x) = \mathrm{Tr}(xR(x)),$$

defines on the $\mathbb{F}_2$-vector space $\mathbb{F}_{q=2^m}$ a quadratic form over $\mathbb{F}_2$ in m variables. In the sequel we denote $Q_R(x)$ simply by $Q(x)$. The associated symmetric bilinear form

$$B(x, y) = \mathrm{Tr}(xR(y) + yR(x)),$$

which is also symplectic, has *radical*

$$W = \{x \in \mathbb{F}_q : B(x, y) = 0 \quad \text{for all} \quad y \in \mathbb{F}_q\}.$$

This $\mathbb{F}_2$-vector space W has dimension w with $m - w \equiv 0 (\mathrm{mod}\, 2)$ since B is symplectic. If $a_h \neq 0$ then $0 \leq w \leq 2h$ (see [G-V1]). Quadratic forms Q and Q' in $\mathbb{F}_2[x_1, ..., x_m]$ which can be obtained from each other by a coordinate transformation are called *equivalent quadratic forms*, denoted by $Q \sim Q'$. We define the *rank* of Q by

$$\mathrm{rk}(Q) = \min_{Q' \sim Q} \{\text{number of variables actually occuring in } Q'\}.$$

In characteristic 2 the quadratic form $Q(x)$ is not necessarily zero on the radical W. Therefore we introduce

$$W_0 = \{x \in W : Q(x) = 0\}$$

and we recall from [G-V1] that $\dim(W_0) = \dim(W)$ or $\dim(W_0) = \dim(W) - 1$. The theory of quadratic forms in characteristic 2 (see [A]) yields

(2.1) Proposition. *The quadratic form* $Q(x) = \mathrm{Tr}(xR(x))$, *with* $R \in R_h - \{0\}$, *has rank* $m - w$ *or* $m - w + 1$ *according to* $W_0 = W$ *or* $W_0 \neq W$. □

Over $\mathbb{F}_2$ the classification of quadratic forms $Q(x)$ is strongly related to the number of zeros $N(Q) = \#\{x \in \mathbb{F}_q : Q(x) = 0\}$ (see [L-N, Ch. 6]). Indeed, we have:

(2.2) Proposition. *If* $Q(x)$ *has rank* $m - w + 1$ *(odd) then*

$$Q(x) \sim X_1X_2 + ... + X_{m-w-1}X_{m-w} + X_{m-w+1}^2 \quad \text{and}$$
$$N(Q) = 2^{w-1} \cdot 2^{m-w} = q/2.$$

If $Q(x)$ *has rank* $m - w$ *(even) then either*

$$Q(x) \sim X_1X_2 + ... + X_{m-w-1}X_{m-w} \quad \text{and}$$
$$N(Q) = 2^w(2^{m-w-1} + 2^{(m-w-2)/2}) = (q + \sqrt{q2^w})/2,$$

or

$$Q(x) \sim X_1X_2 + ... + X_{m-w-1}X_{m-w} + X_{m-w-1}^2 + X_{m-w}^2 \quad \text{and}$$
$$N(Q) = 2^w(2^{m-w-1} - 2^{(m-w-2)/2}) = (q - \sqrt{q2^w})/2.$$

□

We have simple relations for the weight of a word $c_R \in \mathcal{C}_h$ and the number of rational points on the corresponding curve:

$$w(c_R) = q - N(\mathrm{Tr}(xR(x))) \quad \text{and} \quad \#C_R(\mathbb{F}_q) = 2N(\mathrm{Tr}(xR(x))) + 1. \tag{5}$$

(2.3) Remark. Words in $\mathcal{C}_h$ with $w = 2h$ or $w = 2h - 1$ correspond to R of degree 2^h, which means that the corresponding curves have genus 2^{h-1}.

§3. The construction of low weight subcodes of $\mathcal{C}_h$ for odd m.

In this section we take $q = 2^m$ with m odd, $m \geq 3$. To find minimum weight subcodes in $\mathcal{C}_h$ with $0 < h \leq (m-1)/2$ we exploit the following simple observation.

(3.1) Proposition. *For* $0 \leq w \leq 2h - 1$ *with* $m - w \equiv 0 (\mathrm{mod}\ 2)$ *the expression*

$$\sum_{i=1}^{(m-w)/2} \mathrm{Tr}(a_ix)\mathrm{Tr}(b_ix) \tag{6}$$

with $\{a_i, b_i : i = 1, ..., (m-w)/2\} \subset \mathbb{F}_q$ *independent over* $\mathbb{F}_2$, *is a quadratic form which is equivalent to* $X_1X_2 + ... + X_{m-w-1}X_{m-w}$ *and which has* $(q + \sqrt{q2^w})/2$ *zeros in* $\mathbb{F}_q$.

Proof. Since $\mathrm{Tr}(ax) \in \mathbb{F}_2[x_1, ..., x_m]$ is a linear form, (6) is indeed a quadratic form. The $\mathbb{F}_2$-independence of $\{a_i, b_i\}$ implies that the matrix of the transformation $X_{2i-1} = \mathrm{Tr}(a_ix)$ and $X_{2i} = \mathrm{Tr}(b_ix)$ for $i = 1, ..., (m-w)/2$ has rank $m - w$. This matrix can be completed to a coordinate transformation in the m-dimensional $\mathbb{F}_2$-vector space $\mathbb{F}_q$ which yields the equivalence. The number of zeros follows from Proposition (2.2). □

We shall denote the quadratic form (6) by $Q(a_1, ..., a_{(m-w)/2}, b_1, ..., b_{(m-w)/2})$ or simply by $Q(a, b)$. The form $Q(a, b)$ evaluated on $\mathbb{F}_q^*$ induces a word of length $q-1$ and often we shall identify the word and the form. If the $\mathbb{F}_2$-rank of the set

$$\{a_1, ..., a_{(m-w)/2}, b_1, ..., b_{(m-w)/2}\},$$

which we shall also shortly denote by $\{a, b\}$, is $m-w$ then $Q(a, b)$ has weight $(q - \sqrt{q2^w})/2$.

First we derive a criterion for words induced by $Q(a, b)$ to be in $\mathcal{C}_h$.

(3.2) Proposition. *If the elements $a_i, b_i \in \mathbb{F}_q$ with $1 \leq i \leq (m-w)/2$ satisfy the system of equations*

$$\sum_{i=1}^{(m-w)/2} (a_i^{2^j} b_i + a_i b_i^{2^j}) = 0 \tag{7}$$

for $j = h+1, ..., (m-1)/2$, then the word of length $q-1$ induced by evaluating $\sum_{i=1}^{(m-w)/2} \mathrm{Tr}(a_i x)\mathrm{Tr}(b_i x)$ on $\mathbb{F}_q^*$ is a codeword in $\mathcal{C}_h$.

Proof. Observe that for $a, b \in \mathbb{F}_q$ we have

$$\mathrm{Tr}(ax)\mathrm{Tr}(bx) = \mathrm{Tr}(\mathrm{Tr}(ax)bx) = \mathrm{Tr}(\sum_{j=0}^{m-1} a^{2^j} b x^{2^j+1}).$$

The trace map on $\mathbb{F}_q$ satisfies

$$\mathrm{Tr}(a^{2^j} b x^{2^j+1}) = \mathrm{Tr}(a b^{2^{m-j}} x^{2^{m-j}+1})$$

which implies that

$$\mathrm{Tr}(ax)\mathrm{Tr}(bx) = \mathrm{Tr}(\sum_{j=0}^{(m-1)/2} (a^{2^j} b + a b^{2^j}) x^{2^j+1}).$$

The argument of Tr must be of the form $xR(x)$ with $R \in R_h$, hence we do not want terms x^{2^j+1} with $j > h$ to appear in the argument of Tr. This condition yields the system of equations (7). □

(3.3) Corollary. *For fixed $a_1, ..., a_{(m-w)/2}$ the words $Q(a, b)$ induced by the solutions $(b_1, ..., b_{(m-w)/2})$ of (7) form a subcode of $\mathcal{C}_h$.*

Proof. From the linearized character of (7) in the b_i we immediately see that the set of solutions $(b_1, ..., b_{(m-w)/2}) \in \mathbb{F}_q^{(m-w)/2}$ is a $\mathbb{F}_2$-subspace of $\mathbb{F}_q^{(m-w)/2}$. □

For the sequel we fix a $\mathbb{F}_2$-independent subset $\{a_i : 1 \leq i \leq (m-w)/2\}$ of $\mathbb{F}_q$ and we may assume $a_1 = 1$, which is not a restriction because the equations in (7) are homogeneous. Furthermore, we assume that the system of equations is not empty. Since we are especially interested in subcodes consisting of minimum weight words we take $w = 2h-1$ and we put $(m-w)/2 = (m-2h+1)/2 = M$. In this situation we have $M-1$ equations with M unknowns b_i.

(3.4) Proposition. *For fixed $a_1, a_2, ..., a_M$ in $\mathbb{F}_q$ the system of equations (7) has at least q solutions $(b_1, b_2, ..., b_M)$ in $\mathbb{F}_q^M$.*

Proof. If we take an equation $b_1^{2^j} + b_1 = \sum_{i=2}^{M} a_i b_i^{2^j} + a_i^{2^j} b_i$ from (7) and if we apply the transformation $b_1 = b_1' + \sum_{i=2}^{M} \sqrt[2^j]{a_i} b_i$ then this equation becomes

$$b_1'^{2^j} + b_1' = \sum_{i=2}^{M} (a_i^{2^j} + \sqrt[2^j]{a_i}) b_i. \tag{8}$$

Note that (8) has q^{M-1} solutions if at least one of the coefficients of the b_i on the right side is non-zero. Otherwise the number of solutions depends on the number of solutions of $X^{2^j} + X = 0$ in $\mathbb{F}_q$ and is at least $2q^{M-1}$. So the dimension of the $\mathbb{F}_2$-vector space of solutions of an equation from (7), with mM unknowns over $\mathbb{F}_2$, is at least $m(M-1)$. Since we have $M-1$ equations our assertion follows. □

The actual number of solutions of our system depends on the choice of the a_i as we shall see in examples in the next section. To solve the system (7) we repeatedly carry out transformations as described in the proof of Proposition (3.4) and then finally we arrive at an equation of the form

$$S(y) = R(x),$$

where S and R are $\mathbb{F}_2$-linearized polynomials with coefficients in $\mathbb{F}_q$. This equation can be solved by lowering the degree step by step. If degree $(S) \leq$ degree (R) we start with the substitution $y = y' + f(x)$ with a suitable 2-linearized polynomial f. As long as the resulting polynomials are not zero we continue the descent until we arrive at a linear equation in two unknowns which has q solutions.

To obtain words of minimum weight in $\mathcal{C}_h$ we must have solutions $(b_1, ..., b_M)$ of (7) where $\mathrm{rk}_{\mathbb{F}_2}(\{a, b\}) = 2M$.

(3.5) Proposition. *Let $(b_1, ..., b_M)$ be a solution of (7). Then we have:*

$$\mathrm{rk}_{\mathbb{F}_2}(\{a_1, ..., a_M, b_1\}) = M + 1 \quad \textit{implies} \quad \mathrm{rk}_{\mathbb{F}_2}(\{a_1, ..., a_M, b_1, ..., b_M\}) = 2M.$$

Proof. Denote $\sum_{i=1}^{M} \mathrm{Tr}(a_i x)\mathrm{Tr}(b_i x) \in \mathcal{C}_h$ by $\sum_{i=1}^{M} X_{2i-1}X_{2i}$. Assume that $\{a, b\}$ has $\mathbb{F}_2$-rank $< 2M$ with $b_M \in < a_1, .., a_M, b_1, ..., b_{M-1} >$, the $\mathbb{F}_2$-subspace of $\mathbb{F}_q$ generated by the elements between the pointed brackets. This implies $X_{2M} = \sum_{i=1}^{2M-1} \alpha_i X_i$ with $\alpha_i \in \mathbb{F}_2$ not all zero. Then

$$\sum_{i=1}^{M} X_{2i-1}X_{2i} = \sum_{i=1}^{M-1} (X_{2i-1} + \alpha_{2i} X_{2M-1})(X_{2i} + \alpha_{2i-1} X_{2M-1}) +$$

$$+ (\alpha_{2M-1} + \sum_{i=1}^{M-1} \alpha_{2i-1}\alpha_{2i}) X_{2M-1}^2.$$

Note that $X_{2M-1}^2 = (\mathrm{Tr}(a_M x))^2 = (\mathrm{Tr}(a_M x)^2) \in \mathcal{C}_h$ and so

$$\sum_{i=1}^{M-1} (X_{2i-1} + \alpha_{2i} X_{2M-1})(X_{2i} + \alpha_{2i-1} X_{2M-1}) = \sum_{i=1}^{M-1} \mathrm{Tr}(\alpha_i^{(1)} x)\mathrm{Tr}(b_i^{(1)} x) \in \mathcal{C}_h.$$

Here $a_i^{(1)} = a_i + \alpha_{2i} a_M$ and $b_i^{(1)} = b_i + \alpha_{2i-1} a_M$ for $1 \le i \le M-1$ while

$$\mathrm{rk}_{\mathbb{F}_2}(\{a_i^{(1)}, b_i^{(1)} : 1 \le i \le M-1\}) \le 2M-2.$$

If $\mathrm{rk}_{\mathbb{F}_2}(\{a_i^{(1)}, b_i^{(1)} : 1 \le i \le M-1\}) = 2M-2$ we have found a word in $\mathcal{C}_h$ of weight $(q - \sqrt{q2^{2h+1}})/2$ which is smaller than the minimum weight. On the other hand if the $\mathbb{F}_2$-rank of $\{a_i^{(1)}, b_i^{(1)} : 1 \le i \le M-1\} < 2M-2$ we repeat the foregoing procedure. In the end we arrive at a non-zero word

$$\mathrm{Tr}((a_1 + L_1(a_2, ..., a_m))x)\mathrm{Tr}(b_1 + L_2(a_2 ..., a_m))x) \in \mathcal{C}_h,$$

with $\mathbb{F}_2$-linear combinations L_1 and L_2 of $a_2, ..., a_m$, which also violates the minimum weight. □

Let S be the $\mathbb{F}_2$-vector space of solutions $(b_1, ..., b_M)$ of (7) and V the image in $\mathbb{F}_q$ of the projection of S on the first coordinate b_1.

(3.6) Theorem. *If $r = \dim_{\mathbb{F}_2}(V) - M > 0$ then there exists a minimum weight subcode of $\mathcal{C}_h$ of dimension r.*

Proof. Since $r = \dim_{\mathbb{F}_2}(V) - M > 0$ we can find $b_1^{(1)}, ..., b_1^{(r)}$ in V such that

$$\mathrm{rk}_{\mathbb{F}_2}(\{a_1, ..., a_M, b_1^{(1)}, ..., b_1^{(r)}\}) = M + r.$$

By Proposition (3.5) the corresponding solutions $\left(b_1^{(i)}, b_2^{(i)}, ..., b_M^{(i)}\right)$ for $i = 1, ..., r$ induce words of minimum weight in $\mathcal{C}_h$. These words generate a r-dimensional subcode of minimum weight. □

From Proposition (3.4) we derive that $\dim_{\mathbb{F}_2}(S) \ge m$. The following proposition provides us with a lower bound for $\dim_{\mathbb{F}_2}(V)$.

(3.7) Proposition. *Let $(b_1, b_2, ..., b_M) \in S$ then $(b_1, b_2', ..., b_M') \in S$ if and only if $(b_2', ..., b_M') = (b_2, ..., b_M) + (a_2, ..., a_M)A$, where A is a symmetric $(M-1) \times (M-1)$ matrix over $\mathbb{F}_2$.*

Proof. The 'if-part' follows immediately by substitution in (7). For the 'only if - part' we observe that

$$\mathrm{Tr}(a_i x)\mathrm{Tr}((b_i + b_i')x) \tag{9}$$

represents a word in $\mathcal{C}_h$. Just as in the proof of Proposition (3.5) this implies that for $i = 2, ..., M$ the $(b_i + b_i')$ are $\mathbb{F}_2$-dependent of $\{a_2, ..., a_M\}$ or $b_i + b_i' = \sum_{j=2}^{M} \alpha_{ij} a_j$.

By substitution in (9) we obtain

$$\sum_{i=2}^{M} \alpha_{ii}(\mathrm{Tr}(a_i x))^2 + \sum_{i=2}^{M-1} \mathrm{Tr}(a_i x)\mathrm{Tr}((\sum_{i<j\le M} \beta_{ij} a_j)x) \tag{10}$$

with $\beta_{ij} = \alpha_{ij} + \alpha_{ji}$. The second term in (10) also represents a word in $\mathcal{C}_h$. Again to avoid contradiction with the minimum weight in $\mathcal{C}_h$ we must have that $\sum_{i<j\leq M} \beta_{ij} a_j$ is dependent of $a_2, ..., a_{M-1}$ for $i = 2, ..., M$. We then find successively : $\beta_{i,M} = 0$ for $2 \leq i \leq M-1, \beta_{i,M-1} = 0$ for $2 \leq i \leq M-2$ until $\beta_{23} = 0$. This means that the $(M-1) \times (M-1)$ matrix $A = (\alpha_{ij})$ is symmetric. □

Since we can choose $M(M-1)/2$ entries in A independently we have:

(3.8) Corollary. *The dimension of V over $\mathbb{F}_2$ satisfies*

$$\dim_{\mathbb{F}_2}(V) = \dim_{\mathbb{F}_2}(S) - \binom{M}{2} \geq m - \binom{M}{2}. \qquad \square$$

In the following section we shall illustrate the ideas and results of this section by some examples.

§4. Determination of generalized Hamming weights and curves with many points.

We have

$q = 2^m$ with $m \geq 3$ odd,
$0 < h \leq (m-1)/2$,
$w = 2h - 1$ and
$M = (m - 2h + 1)/2$.

I. *The case $h = (m-1)/2$.*

Since the system (7) is empty, Propositions (3.1) and (3.2) imply that $\mathrm{Tr}(x)\mathrm{Tr}(bx) \in \mathcal{C}_h$ and has minimum weight for $b \in \mathbb{F}_q - \mathbb{F}_2$. By choosing $\mathbb{F}_2$-independent elements $b^{(1)}, ..., b^{(m-1)}$ in $\mathbb{F}_q$ we find words which generate a $(m-1)$-dimensional subcode of $\mathcal{C}_h$ of minimum weight. Combining (4) and Proposition (2.2) we find:

(4.1) Proposition. *The generalized Hamming weights of the binary code $\mathcal{C}_{(m-1)/2}$ of length $2^m - 1$ satisfy*

$$d_r(\mathcal{C}_{(m-1)/2}) = (2^r - 1) \cdot 2^{m-r-1} \quad \textit{for} \quad 1 \leq r \leq m-1. \qquad \square$$

Applying the fibre product construction from §1 to these minimum weight subcodes we get:

(4.2) Corollary. *For $1 \leq r \leq m-1$ there exist curves C_r defined over $\mathbb{F}_q$ of genus $g(C_r) = (2^r - 1)2^{(m-3)/2}$ and $\#C_r(\mathbb{F}_q) = 2^m + 1 + (2^r - 1)2^{m-1}$.*

Proof. The curves corresponding to the non-zero words in the r-dimensional minimum weight subcode $\mathcal{D}_r$ have genus $g = 2^{h-1} = 2^{(m-3)/2}$ and according to (5) $t_{\mathrm{Frob}} = q - 2N(Tr(xR(x)) = -\sqrt{q2^{2h-1}}$.

From (2) and (3) we obtain $g(C^{(\mathcal{D}r)}) = (2^r - 1)2^{(m-3)/2}$ and

$$\#C^{(\mathcal{D}r)}(\mathbb{F}_q) = q + 1 + (2^r - 1)\sqrt{q2^{2h-1}} = 2^m + 1 + (2^r - 1)2^{m-1}. \qquad \square$$

This result confirms our earlier result [G-V3, Thm. 5].

II. *The case* $h = (m-3)/2$.

We take $m \geq 5$. In this case $M = 2$; fix $\{1, a_2\}$ with $\mathbb{F}_2$-rank 2 in $\mathbb{F}_q$. The system (7) consists of the equation

$$b_1^{2^{(m-1)/2}} + b_1 = a_2 b_2^{2^{(m-1)/2}} + a_2^{2^{(m-1)/2}} b_2. \tag{11}$$

The transformation $b_1 = b_1' + \sqrt[2^{(m-1)/2}]{a_2}\, b_2$ changes (11) into

$$b_1'^{2^{(m-1)/2}} + b_1' = \big(a_2^{2^{(m-1)/2}} + \sqrt[2^{(m-1)/2}]{a_2}\big) b_2. \tag{12}$$

The coefficient of b_2 in (12) is non-zero because $\{1, a_2\}$ has $\mathbb{F}_2$-rank 2. Hence (11) has q solutions (b_1, b_2) or $\dim_{\mathbb{F}_2}(S) = m$. From Corollary (3.8) we deduce $\dim_{\mathbb{F}_2}(V) = m-1$ and we find by Theorem (3.6):

(4.3) Proposition. *i) The generalized Hamming weights of* $\mathcal{C}_{(m-3)/2}$ *of length* $2^m - 1$ *satisfy*

$$d_r(\mathcal{C}_{(m-3)/2}) = (2^r - 1)(2^{m-1} - 2^{m-3})/2^{r-1} \quad \textit{for} \quad 1 \leq r \leq m-3.$$

ii) For $1 \leq r \leq m-3$ *there exist curves* C_r *defined over* $\mathbb{F}_{2^m}$*, with* $m \geq 5$ *odd, of genus* $g(C_r) = (2^r - 1)2^{(m-5)/2}$ *and with* $\#C_r(\mathbb{F}_{2^m}) = 2^m + 1 + (2^r - 1)2^{m-2}$.

Proof. The proof is similar to the proof of Proposition (4.1) and Corollary (4.2). □

(4.4) Example. For $m = 7$ we have $h = 2$ and $\mathcal{C}_2 = BCH(3)^\perp$, the dual of the 3-error correcting BCH code of length 127. The former Proposition yields:

- *The generalized Hamming weights* $d_r, 1 \leq r \leq 4$, *of* $BCH(3)^\perp$ *of length* 127 *are*

$$d_1 = 48, \quad d_2 = 72, \quad d_3 = 84, \quad d_4 = 90.$$

- *There exists curves* C_r *defined over* $\mathbb{F}_{128}$ *with*

r	$g(C_r)$	$\#C_r(\mathbb{F}_{128})$	Wirtz
1	2	161	$(184 - 195)$
2	6	225	$(225 - 261)$
3	14	353	$(289 - 437)$
4	30	609	$(369 - 789)$.

III. *The case* $h = (m-5)/2$.

We take $m \geq 7$. In this case $M = 3$; fix $\{1, a_2, a_3\}$ $\mathbb{F}_2$-independent in $\mathbb{F}_q$. The system of equations is:

$$b_1^{2^{(m-3)/2}} + b_1 = \sum_{i=2,3} \left(a_i b_i^{2^{(m-3)/2}} + a_i^{2^{(m-3)/2}} b_i \right), \tag{13}$$

$$b_1^{2^{(m-1)/2}} + b_1 = \sum_{i=2,3} \left(a_i b_i^{2^{(m-1)/2}} + a_i^{2^{(m-1)/2}} b_i \right). \tag{14}$$

Apply the linear transformation $b_1 = b_1' + \sqrt[s]{a_2}b_2 + \sqrt[s]{a_3}b_3$ with $s = 2^{(m-1)/2}$. Equation (14) becomes linear in b_2 and b_3 with non-zero coefficients. We express b_3 in b_1' and b_2. Then (13) becomes an equation in b_1' and b_2 of the form $S(b_1') = R(b_2)$ with R and S 2-linearized. In general $S(b_1')$ has degree 2^{m-2} and $R(b_2)$ has degree $2^{(m-3)/2}$ and we find q solutions (b_1, b_2, b_3) (see the remarks after Proposition (3.4)). Just as in the cases I and II we find a proposition on generalized Hamming weights and on curves.

The existence of q solutions is guaranteed by Proposition (3.4). However for special choices of $\{1, a_2, a_3\}$ the number of solutions is a multiple of q. To illustrate this remark we consider the following example.

(4.5) Example. For $m = 9$ and $h = 2$ our system is:

$$b_1^8 + b_1 = a_2 b_2^8 + a_2^8 b_2 + a_3 b_3^8 + a_3^8 b_3, \tag{15}$$

$$b_1^{16} + b_1 = a_2 b_2^{16} + a_2^{16} b_2 + a_3 b_3^{16} + a_3^{16} b_3. \tag{16}$$

Now we choose a special $\mathbb{F}_2$-independent triple: $\{1, a_2, a_3\} \subset \mathbb{F}_8$. Then we can write (15) as

$$b_1^8 + b_1 = a_2^8 b_2^8 + a_2 b_2 + a_3^8 b_3^8 + a_3 b_3. \tag{17}$$

The solutions of (17) are $\{(b_1, b_2, b_3) \in \mathbb{F}_{512}^3 : b_1 + a_2 b_2 + a_3 b_3 = \mu \in \mathbb{F}_8\}$. Take a value $\mu \in \mathbb{F}_8$ and substitute $b_1 = \mu + a_2 b_2 + a_3 b_3$ in (16). We find an equation in b_2 and b_3 which has q solutions (b_2, b_3), so the original system has $8q$ solutions and $\dim_{\mathbb{F}_2}(S) = 12$. Then Corollary (3.8) and Theorem (3.6) yield:

- *The generalized Hamming weights d_r of $BCH(3)^\perp$ of length 511 satisfy*

$$d_r = (2^r - 1)d_1/2^{r-1} = 224(2^r - 1)/2^{r-1} \quad \textit{for} \quad 1 \le r \le 6.$$

- *There exist curves C_r defined over $\mathbb{F}_{512}$ with*

r	$g(\mathcal{C}_r)$	$\#C_r(\mathbb{F}_{512})$	*Upper bound (1)*
1	2	577	603
2	6	705	783
3	14	961	1143
4	30	1473	1863.

Combination of the cases also produce good curves as we shall show by an example.

(4.6) Example. Take $m = 7$ and fix $\mathbb{F}_2$-independent $\{1, a_2\}$ in $\mathbb{F}_{128}$. By Proposition (4.3) in case II there exists a word of minimum weight in $\mathcal{C}_2$, which is 48, of the form $\mathrm{Tr}(x)\mathrm{Tr}(b_1 x) + \mathrm{Tr}(a_2 x)\mathrm{Tr}(b_2 x)$. Now $c_1 = \mathrm{Tr}(x)\mathrm{Tr}(b_1 x)$ and $c_2 = \mathrm{Tr}(a_2 x)\mathrm{Tr}(b_2 x)$ are words in $\mathcal{C}_3$ since in the corresponding $\mathrm{Tr}(xR(x))$ the degree of $xR(x)$ is equal to $2^{(m-1)/2} + 1 = 9$. From Proposition (2.2) it follows that c_1 and c_2 have weight 32. The curves corresponding to c_1, c_2 and $c_1 + c_2$ have genus $4, 4, 2$ respectively and trace of Frobenius $-64, -64, -32$ respectively. So the fibre product curve corresponding to the subcode of $\mathcal{C}_3$ generated by c_1 and c_2 is a curve over $\mathbb{F}_{128}$ of genus $g = 10$ and $129 + 160 = 289$ rational points. The upper bound (1) in this case is 349.

Applying the same approach to a word

$$\mathrm{Tr}(x)\mathrm{Tr}(b_1 x) + \mathrm{Tr}(a_2 x)\mathrm{Tr}(b_2 x) + Tr(a_3 x)Tr(b_3 x)$$

of minimum weight in $\mathcal{C}_1$ over $\mathbb{F}_{128}$ one finds a curve of genus $g = 9$ with 241 rational points (Wirtz: 209-327).

§5. The construction of low weight subcodes of $\mathcal{C}_h$ for even m.

For even m the situation is somewhat more complicated as we shall explain in this section.

We take $q = 2^m$ with m even, $m \geq 4$ and we consider the code $\mathcal{C}_h$ with $0 < h < m/2$. Words in $\mathcal{C}_h$ correspond to quadratic forms with $0 \leq w \leq 2h$ and $m - w \equiv 0 (\mathrm{mod} 2)$.

In the same way as in Proposition (3.2) we find a system of equations as condition for $\sum_{i=1}^{(m-w)/2} \mathrm{Tr}(a_i x)\mathrm{Tr}(b_i x)$ to induce a word in $\mathcal{C}_h$. For $j = h+1, ..., (m-2)/2$ the equations are of the same form as in (7) but for $j = m/2$ we find a term $a^{2^{m/2}} b x^{2^{m/2}+1}$ in the expansion of $\mathrm{Tr}(ax)\mathrm{Tr}(bx)$ which we want to neglect. To achieve that we could require

$$\sum_{i=1}^{(m-w)/2} a_i^{2^{m/2}} b_i = 0.$$

However, note that $\mathrm{Tr}(x^{2^{m/2}+1}) = 0$ for $x \in \mathbb{F}_q$ since $x^{2^{m/2}+1} \in \mathbb{F}_{\sqrt{q}}$. So we can also disregard the term with $x^{2^{m/2}+1}$ if we require $\sum_{i=1}^{(m-w)/2} a_i^{2^{m/2}} b_i \in \mathbb{F}_{\sqrt{q}}$ or if we require $\sum_{i=1}^{(m-w)/2} \left(a_i^{2^{m/2}} b_i + a_i b_i^{2^{m/2}}\right) = 0$ which is less restrictive than $\sum_{i=1}^{(m-w)/2} a_i^{2^{m/2}} b_i = 0$ and of the same form as the other equations. For completeness sake we formulate the counterpart of Proposition (3.2).

(5.1) Proposition. *If the elements $a_i, b_i \in \mathbb{F}_q$ with $1 \leq i \leq (m-w)/2$ satisfy the system of equations*

$$\sum_{i=1}^{(m-w)/2} \left(a_i^{2^j} b_i + a_i b_i^{2^j}\right) = 0 \tag{18}$$

for $j = h+1, ..., m/2$, then $\sum_{i=1}^{(m-w)/2} \mathrm{Tr}(a_i x)\mathrm{Tr}(b_i x)$ induces a codeword in $\mathcal{C}_h$. □

Words of minimum weight in $\mathcal{C}_h$ correspond to quadratic forms with $w = 2h$ and we set $M = (m-2h)/2$. Furthermore, we fix a $\mathbb{F}_2$-independent subset $\{a_i : 1 \leq i \leq M\} \subset \mathbb{F}_q$, and if we wish we may assume that $a_1 = 1$. The situation is complicated by the fact that (18) has M equations in M unknowns b_i hence we cannot guarantee the existence of q solutions $(b_1, ..., b_M)$ as in the odd case. By successively applying linear transformations to (18) we finally arrive at an equation of the form $S(x) = 0$ with S a 2-linearized polynomial. The actual number of solutions of (18) depends on the choice of the subset $\{a_i : 1 \leq i \leq M\}$.

To find generalized Hamming weights of $\mathcal{C}_h$ and curves with many points we employ the same strategy as indicated in Section 3. The reader can easily convince himself that for even m we have the analogues of (3.5), (3.6), (3.7) and (3.8). We shall illustrate the strategy by working out some examples

I. *The case* $h = (m-2)/2$.

The system (18) consists of only one equation:

$$b_1^{2^{m/2}} + b_1 = 0$$

which has $2^{m/2}$ solutions or $\dim_{\mathbb{F}_2}(S) = m/2$. We find by Theorem (3.6):

(5.2) Proposition. *i). The generalized Hamming weights of $\mathcal{C}_{(m-2)/2}$ of length $2^m - 1$ satisfy $d_r(\mathcal{C}_{(m-2)/2}) = (2^r - 1)(2^{m-1} - 2^{m-2})/2^{r-1}$ for $1 \leq r \leq (m-2)/2$.*
ii) For $1 \leq r \leq (m-2)/2$ there exist curves C_r defined over $\mathbb{F}_{2^m}$ of genus $g(\mathcal{C}_r) = (2^r - 1)2^{(m-4)/2}$ and $\#C_r(\mathbb{F}_q) = 2^m + 1 + (2^r - 1)2^{m-1}$; these curves attain the Hasse-Weil upper bound. □

(5.3) Example. For $m = 6$ we have $h = 2$ and for $\mathcal{C}_2 = BCH(3)^\perp$ of length 63 holds $d_2(BCH(3)^\perp) = \frac{3}{2}d_1(BCH(3)^\perp) = 24$. Furthermore there exists curves $\mathcal{C}_r$ defined over $\mathbb{F}_{64}$ with

r	$g(\mathcal{C}_r)$	$\#C_r(\mathbb{F}_{64})$	Wirtz
1	2	97	97
2	6	161	$155 - 161$

For $m = 8$ we have $h = 3$ and from Proposition (5.2.ii) we obtain curves C_r defined over $\mathbb{F}_{256}$ with

r	$g(\mathcal{C}_r)$	$\#C_r(\mathbb{F}_{256})$	Upper bound (1)
1	4	385	385
2	12	641	641
3	28	1153	1153.

II. *The case* $h = (m-4)/2$.

We take $m \geq 6$. The system of equations is

$$b_1^{2^{m/2-1}} + b_1 = a_2 b_2^{2^{m/2-1}} + a_2^{2^{m/2-1}} b_2,$$
$$b_1^{2^{m/2}} + b_1 = a_2 b_2^{2^{m/2}} + a_2^{2^{m/2}} b_2.$$

If we employ the transformation $b_1 = b_1' + \sqrt[2^{m/2}]{a_2}\, b_2$ we get

$$b_1'^{2^{m/2-1}} + b_1' = \big(a_2 + \sqrt{a_2}\big) b_2^{2^{m/2-1}} + \big(a_2^{2^{m/2-1}} + \sqrt[2^{m/2}]{a_2}\big) b_2,$$
$$b_1'^{2^{m/2}} + b_1' = \big(a_2^{2^{m/2}} + \sqrt[2^{m/2}]{a_2}\big) b_2 = 0. \tag{19}$$

The second equation in (19) implies $b_1' \in \mathbb{F}_{\sqrt{q}}$.

Now we choose $a_2 \in \mathbb{F}_4 - \mathbb{F}_2$ then the first equation in (19) becomes

$$b_1'^{2^{m/2-1}} + b_1' = b_2^{2^{m/2-1}} + b_2.$$

This implies $b_2 = b_1' + \mathbb{F}_2$ if g.c.d. $(m, (m-2)/2) = 1$ or $b_2 = b_1' + \mathbb{F}_4$ if g.c.d. $(m, (m-2)/2) = 2$. We have proved:

(5.4) Proposition. *If we take $\{1, a_2\}$ with $a_2 \in \mathbb{F}_4 - \mathbb{F}_2$ then the system of equations (19) has $2\sqrt{q}$ solutions (b_1, b_2) for $m \equiv 0 (\mathrm{mod}\ 4)$ and $4\sqrt{q}$ solutions for $m \equiv 2 (\mathrm{mod}\ 4)$.* □

We shall leave the formulation of the analogue of (5.2) to the reader. It implies that there exist curves over $\mathbb{F}_{256}$ of genus 2 with 321 points and of genus 6 with 449

points; both values are maximal. Moreover $d_2(BCH(3)^\perp) = \frac{3}{2}d_1(BCH(3)^\perp) = 144$ for $BCH(3)^\perp$ of length 255.

Finally, it is also possible to obtain good curves by applying the method to a combination of the cases. We shall illustrate this with an example.

(5.5) Example. Take $m = 6$ and let $\rho \in \mathbb{F}_4 - \mathbb{F}_2$. As we saw in case I the word $\mathrm{Tr}(x)\mathrm{Tr}(bx) \in \mathcal{C}_2$ if $b^8 + b = 0$, i.e. $b \in \mathbb{F}_8$. On the other hand case II implies that $\mathrm{Tr}(x)\mathrm{Tr}(bx) + \mathrm{Tr}(\rho x)\mathrm{Tr}(b_2 x) \in \mathcal{C}_1$ if

$$\begin{aligned} b_1^4 + b_1 &= \rho b_2^4 + \rho b_2, \\ b_1^8 + b_1 &= \rho b_2^8 + \rho^2 b_2. \end{aligned} \tag{20}$$

One checks that the solutions (b_1, b_2) of (20) can be written as $(b_1, b_2) = s(\rho, 1) + t(1, \rho)$ with $s \in \mathbb{F}_8, t \in \mathbb{F}_4$. Now choose $b \in \mathbb{F}_8 - \mathbb{F}_2$ and $(b_1, b_2) = b(\rho, 1)$ then $\{1, \rho, b\rho, b\}$ has $\mathbb{F}_2$-rank 4. The corresponding words are

$$c_1 = \mathrm{Tr}(x)\mathrm{Tr}(bx) = \mathrm{Tr}(bx^2 + (b^2 + b)x^3 + (b^4 + b)x^5) \quad \text{of weight} \quad 16,$$

$$c_2 = \mathrm{Tr}(x)\mathrm{Tr}(b\rho x) + \mathrm{Tr}(\rho x)\mathrm{Tr}(bx) = \mathrm{Tr}((b^2 + b)x^3) \quad \text{of} \quad \text{weight} \quad 24.$$

Then $c_1 + c_2 = \mathrm{Tr}(x)\mathrm{Tr}(b\rho^2 x) + \mathrm{Tr}(\rho x)\mathrm{Tr}(bx) = \mathrm{Tr}(bx^2 + (b^4 + b)x^5) \in \mathcal{C}_2$ has weight 24 as follows from Proposition (2.2) since $\{1, \rho, b\rho^2, b\}$ also has $\mathbb{F}_2$-rank 4. The curves have genus $2, 1, 2$ respectively and trace of Frobenius $-32, -16, -16$ respectively. So we find a fibre product curve over $\mathbb{F}_{64}$ of genus 5 with $65 + 64 = 129$ rational points (Wirtz: 101-145).

(5.6) Remark. For $b \in \mathbb{F}_8 - \mathbb{F}_2$ the quadratic form $\mathrm{Tr}(bx^9)$ vanishes on $\mathbb{F}_{64}$. This implies that the curve $y^2 + y = bx^9$ with genus 4 has trace of Frobenius -64. The fibre product of this curve and

$$y^2 + y = bx^9 + (b^4 + b)x^5 + (b^2 + b)x^3 + bx^2$$

has genus $g = 10$ and 193 points over $\mathbb{F}_{64}$ (Wirtz: $139 - 225$)
